

VIDS Governance

Field	Value
Document class	Charter document (Layer 0), see Section 2
Status	Draft, pending Steering Committee adoption (see MD-0002); an Adopted date field is added on acceptance
Drafted	2026-07-12
Maintained by	Steering Committee (Princeton Medical Systems)
Related	CONTRIBUTING.md; SPEC.md; MD-0001; MD-0002; SOP-Governance-Decision-Lifecycle

This document defines how VIDS classifies the documents it produces, which of them may create requirements, and where authority for each lives. It is a charter document: it defines the classification system rather than being classified by it.

1. The Normative Principle

Only the Core Specification (SPEC) creates, modifies, or removes dataset-conformance requirements.

All other document types are informative. They may explain, justify, record, or govern project operation, but they cannot change the normative requirements of VIDS.

This is the governing principle of the entire model. Everything below exists to make it enforceable and unambiguous. A change note, a decision record, an operating procedure, or a registry can inform, decide, or track - but it can never make a dataset conformant or non-conformant. Only SPEC does that, and only through the ratification path in CONTRIBUTING.md.

2. Two categories of document

The repository contains two categories of document.

1. Charter documents (Layer 0 - repository governance). These define the governance and operation of the project itself. They are *not* part of the numbered artifact taxonomy - because they define that taxonomy. They are living repository documents, amended by Steering Committee consensus.

- README.md, GOVERNANCE.md, CONTRIBUTING.md, LICENSE, NOTICE, CODE_OF_CONDUCT.md (if adopted)

2. Project artifacts (Layer 1 - produced under the governance model). These are the documents the project produces, classified by the artifact taxonomy in §4.

- SPEC, MD, CN, SOP, REG

The dependency runs one way, which is what avoids any recursion - no Layer 1 artifact has to define itself:

And the authority stack, top to bottom:

Both the validator and the registries derive their authority from SPEC, but in different ways: the **validator enforces** the specification, while a **registry records and traces** it - inventorying identifiers and mappings. Keeping enforcement and traceability as separate consequences of the same normative source is deliberate. The validator alone is intentionally **not** a document type; it is an implementation artifact governed by the Core Specification. (REG is a Layer 1 document type; it appears in this diagram only to show that its authority, like the validator's, flows from SPEC.) The principle governing what happens when validator behavior and the specification diverge is recorded in MD-0001.

3. Artifact taxonomy at a glance

Code	Name	Purpose	Normative?	Lifecycle	Default visibility
SPEC	Specification	The normative standard: requirements, rules, schemas	Yes	Versioned; changed only via PR + maintainer ratification	Public
MD	Maintainer Decision	A standard-governance decision and its rationale	No	Append-only; superseded, never rewritten	Public
CN	Change Note	Point-in-time record of what changed and its impact	No	Immutable once published; version-tagged	Public
SOP	Standard Operating Procedure	An operational process the project follows	No	Living: Draft → Active → Retired	Internal
REG	Registry	Machine-readable inventory maintained by tooling	No (see §4)	Living; tool-maintained; CI-validated where implemented	Public

4. Artifact type definitions

SPEC - Specification. The authoritative standard. Changes follow the CONTRIBUTING.md decision process (editorial / minor / major) and require maintainer review to merge. Identified by version (e.g., v1.0), not a sequence number. The only normative artifact.

MD - Maintainer Decision. Records a standard-governance decision the maintainers have *made*, and why: scope calls, policy, governance. Forward-looking. Append-only - once accepted, an MD is not rewritten to change its meaning; a later decision that reverses or refines it is a new MD marking the earlier one *Superseded* by MD-NNNN. Correcting a factual error in an MD's description of the world is permitted (dated); changing the *decision* requires a new MD.

MD is standard governance only. MD means *Maintainer Decision*: public, standard-governance. Internal company/PMS management decisions are **out of scope** of this taxonomy and do not share its numbering - they belong to a separate internal track.

CN - Change Note. Records what *changed* and the impact on adopters. Backward-looking. Immutable once published, tagged to the version(s) it describes.

The MD-vs-CN test. MD answers "*what did we decide, and why?*" CN answers "*what changed, and what does it mean for adopters?*" A single governance event may produce several artifact types - for example a SPEC amendment (normative), an MD (the governance decision), and a CN (the adopter-facing impact) - each with a distinct purpose and authority.

Errata are SPEC-internal, not CN. Corrections to released normative text live inside SPEC (§15.3) and dataset-facing CHANGES.md. CN is the adopter-facing *narrative* around a change, not the errata record itself.

SOP - Standard Operating Procedure. How the project operates: release checklists, the pre-tag documentation grep, the identity-discipline routine (confirm the operating account and git identity before any commit/tag/push). Living, ops-owned, freely revised.

REG - Registry. A machine-readable inventory maintained by tooling: continuously updated, consumed by CI, and authoritative for **identifiers and traceability**. Examples: REG-REQ (requirements inventory / §3.2 traceability, requirements.yaml), REG-RULE (validator rule inventory), REG-DOC (the index of all Layer 1 artifacts).

A REG is authoritative for the *identifiers and mappings it holds*, but it is **not** normative for conformance: per §1, only SPEC creates a requirement. A REG records *which* requirement/rule exists and how they trace to each other; SPEC remains the source of the requirement itself. This boundary is deliberate - it stops a registry from becoming a backdoor

normative source.

REG identifiers are **named slugs** (REG-REQ, REG-RULE, REG-DOC), not TYPE-NNNN sequences, because registries are singletons-by-domain. Where CI validation exists, a REG that disagrees with the artifact it inventories is treated as a **build failure**, not a stylistic nit (see Section 8). A REG may exist first as a human-maintained document; machine-readable companions (for example REG-DOC.json) are script-generated derivatives with a divergence-failing verifier, added only when tooling consumes them, and never independently maintained.

5. Visibility

Every Layer 1 artifact declares a **Visibility**: `Public` or `Internal`.

- SPEC, CN, and public registries are **Public**.
- SOP is **Internal** by default.
- MD is **Public** by definition (it is standard governance). Internal company management decisions are not MDs and are not published into the public standard repository.

Internal-visibility content **MUST NOT** be published into the public standard repository.

6. Identifiers and status

Format. TYPE-NNNN - type code, hyphen, zero-padded sequence number (MD-0002, CN-0001), assigned sequentially per type, never reused, immutable once assigned. SPEC is identified by version; REG by named slug.

Status values.

- **SPEC** - by version and release status (Draft / Release).
- **MD** - Proposed → Accepted → (Superseded | Rejected). Acceptance follows the Governance Decision Lifecycle SOP: a Signature Copy with blank sign-off blocks collects approvals; the signed PDF files as immutable approval evidence (MD-NNNN-ApprovalEvidence-YYYY-MM-DD.pdf); the document of record then carries a Proposed date, an Accepted date (the later of the required approvals, never backdated), a completed approval table, and the evidence cited by filename only. The published rendering contains no signature lines.
- **CN** - Draft → Published (immutable thereafter).
- **SOP** - Draft → Active → Retired.
- **REG** - Active → Deprecated.

The **REG-DOC** index lists every Layer 1 artifact with its ID, title, status, and visibility, so the governing set is discoverable - and so its own drift is machine-checkable.

7. Authority

Type	Authored by	Accepted / gated by
Charter docs	Anyone (PR)	Steering Committee consensus
SPEC	Contributors (PR)	Maintainer ratification (per CONTRIBUTING)
MD	Anyone (Proposed)	Maintainer / Steering Committee acceptance
CN	Ops	Accuracy-gated (a CN that misstates the artifact is a defect)
SOP	Ops	Ops owns
REG	Tooling	CI validation where implemented; registry drift treated as a build failure

8. Enforcement

This taxonomy is **filing, not enforcement**. Naming a document "SPEC" does not keep it true. What keeps the normative layer honest is the automated tie between SPEC and the validator - `check_docs.py` (doc rule-counts and descriptions must match the validator) and `check_requirements.py` (every enforced requirement names a real FAIL-severity rule; no orphan rules; no unresolved CONFLICT) - and, for registries, CI validation (where implemented) that treats drift from the inventoried artifact as a build failure.

Consequently: **adding document types must not add drift surface**. Any normative claim is trustworthy only to the extent a check can verify it against the artifact. The taxonomy rides on top of these checks; it does not substitute for them. Structurally: *every statement in the project has a defined authority, and every authoritative statement is checkable against the thing it describes*.

9. Amending this document

GOVERNANCE.md is a charter document. It is amended by Steering Committee consensus, following the same review discipline as a spec change. Adoption of the model it describes is recorded in **MD-0002**.

Change log

Date	Change
2026-07-12	Initial draft (charter and taxonomy), submitted for adoption via MD-0002.
2026-07-26	Pre-adoption revisions: date-field convention applied (Drafted; Adopted date added on acceptance); MD acceptance-record convention added to Section 6 per the Governance Decision Lifecycle SOP; REG derivative rule added to Section 4; punctuation normalized (em-dashes removed). No change to the two-layer model, the Normative Principle, or any artifact-type definition.
